

I want to build a Legal second brain for the user, which solves the problem of mismanaged information logging for lawyers. For instance, a regular lawyer has multiple cases across a day and information (like client's updates, courtroom observations, next dates, and any actionable tasks) comes in pieces and randomly, and it is practically hard for the lawyer to remember everything and equally hard to log the information instantly in a systematic manner, and thus, tracking multiple cases for a litigation lawyer is an arduous and a physical process and is not streamlined and requires a lot of manual retention.

Now, I want to build a platform (An App/Webapp) which has a one tap voice input - the user inputs the information he needs to log (Client's update, Next Date, Actionable Task, General Notes) - The input gets to the AI Agent who then listens and analyses the input, transcribe it and rewrites it in a structured grammatically correct format and most importantly classifies the given input into the mentioned categories (Client's update, Next Date, Actionable Task, General Note) - Now after classifying the given input, the next task is to identify the corresponding case for which the information is being logged (the cases can be stored in card decks), now the notes contain the case name as the metadata which is searchable for the AI Agent to determine the particular case in which such information is intended to be logged (The user will always include the case name in its voice input to help the AI with classification of cases, in absence of sufficient information, the AI shall ping the user to input the case name in which the respective information is to be logged- finally the information is logged into the respective note pertaining to the corresponding matter automatically in a format that is both machine and human friendly to read, so that the note can always be read by the AI, the information log should always contain the respective category (Client's update, Next Date, Actionable Task, General Note) and if the AI has classified the information as a Next Date, a calendar event is created automatically for the pertaining date, after logging the information in the note- if the AI has classified the task as an actionable task, then the AI will set a reminder to help the user keep track of all the actionable tasks - As the information logged by the user grows, I want the information to be systematically presented on the user dashboard where the user can track and read all his case notes, can analyse his actionable task list, can manage his calendar on the dashboard, keep track of payments and invoices etc regarding his own matters - finally the dashboard/UI also contains the AI Chatbox from where the user can chat with the AI and can ask the AI anything regarding the database the user has built - I want the AI to be a general assistant who can overview all the data available across the cases and advise the user on actionable tasks, planning his day, pending bills, pending and desired follow-ups etc, basically serving as a legal brain which holds all the information about the user's professional work.
